NESDIS = Data Provider
NMFS, NOS, NWS and OAR are Data Users

NMFS: National Marine Fisheries Service
NOS: National Ocean Service
NWS: National Weather Service
OAR: Oceanic and Atmospheric Research
Physiographic and satellite derived lower trophic level datasets (i.e. chlorophyll, primary production, and chlorophyll gradients) were statistically analyzed to establish spatial management units, intended for Ecosystem Based Management (R. Gamble & M. Fogarty).

From Hyde et al., poster
Phytoplankton size class and primary production data are used in food web models to estimate fisheries production potential and develop harvest strategies (K. Hyde & M. Fogarty).
Tagged Species

Electronic tagging is a key methodology used by NOAA Fisheries to gather information on stock productivity and recruitment, fish behavior, feeding ecology and habitat selection—information needed for accurate and responsible fisheries management.¹

Satellite data, such as ocean color, SST, SSH and SVW, are necessary to place the telemetric data from tags in an environmental context as part of the transition to an ecosystem approach to management.

Summary

1. Management of highly migratory species is reliant on spatially and temporally explicit information on their distribution and abundance. Satellite telemetry provides time-series data on individual movements. However, these data are underutilized in management applications in part because they provide presence-only information rather than abundance information such as density.

2. Eastern North Pacific blue whales are listed as threatened, and ship strikes have been suggested as a factor limiting their recovery. Here, we developed a satellite-telemetry-based habitat model in a case-control design for Eastern North Pacific blue whales Balaenoptera musculus that was combined with previously published abundance estimates to predict habitat preference and densities. Further, we operationalized an automated, near-real-time whale density prediction tool based on up-to-date environmental data for use by managers and other stakeholders.

3. A switching space-time model was applied to 104 blue whale satellite tracks from 1994 to 2008 to account for errors in the location estimates and provide daily positions (case points). We simulated positions using a correlated random walk model (control points) and sampled the environment at each case and control point. Generalized additive mixed models and boosted regression trees were applied to determine the probability of occurrence based on environmental covariates. Models were used to predict 8-day and monthly resolution, year-round density estimates scaled by population abundance estimates that provide a critical tool for understanding seasonal and interannual changes in habitat use.

4. The telemetry-based habitat model predicted known blue whale hot spots and had seasonal agreement with sightings data, highlighting the skill of the model for predicting blue

Predicted catch + Predicted bycatch → EcoCast

Using satellite data, areas optimized for fish catch and minimal bycatch can be predicted in near-real time for use by managers and fishers. Currently a RShiny app is under development. A NASA funded project.

Salmon Survival in 2011

Adult Chinook Returns – What happened in 2011?

Time series of average April-May chlorophyll concentrations in coastal Gulf of Alaska. The lowest value (2011) suggests that low productivity could have negatively influenced salmon survival that year.
NRT Cruise support

- VIIRS chl image generated by NESDIS in support of a SEFSC survey cruise looking for bluefin tuna larvae.
- Images are used to position stations to cover frontal features, small and mesoscale oceanographic features, and to ensure as many different water masses as possible are sampled.
- They requested the images in gray scale.

Gulf of Mexico Harmful Algal Bloom Bulletin
Region: Southwest Florida
Monday, 24 October 2016
NOAA National Ocean Service
NOAA Satellite and Information Service
NOAA National Weather Service
Last bulletin: Thursday, October 20, 2016

Conditions Report
Not present to high concentrations of Karenia brevis (commonly known as Florida red tide) are present along- and offshore portions of southwest Florida, and not present in the Florida Keys. K. brevis concentrations are patchy in nature and levels of respiratory irritation will vary locally based upon nearby bloom concentrations, ocean currents, and wind speed and direction. The highest level of potential respiratory irritation forecast for Monday, October 24 through Thursday, October 27 is listed below:

Innovations

Increments
• 3-day (free!) course aimed at NMFS or NOS participants (the “wet” side of NOAA) who want to learn how to access & use satellite data

• Objective is to help people access and use satellite data in the environment they are used to working in – a challenging task! Focus has been on GIS, Matlab and R applications.

• Participants bring projects to work on.

• Course initiated by funding from NOAA’s R&O project in 2006. The JPSS program has provided full or partial funding since 2013-2015.

• The learning experience goes two ways. From conducting these courses we get a better idea of users’ needs and wants, and therefor are better able to address those needs.

http://coastwatch.pfeg.noaa.gov/courses/satellite_course2017.html
Take Home Points

• Within NMFS, NOS and NWS, ocean color data is used in a variety of different applications, many of which are not a NRT or 24/7 usage. Examples include:
  − Predicting and Monitoring HABs (NOS)
  − Characterizing sanctuaries and MPA (NOS)
  − Optimizing assessment surveys (NMFS)
  − Improving Stock Assessments (NMFS)
  − Characterizing Animal Habitat (NMFS)
  − Dynamic Ocean Management (NMFS)
  − Modeling & Data Assimilation (NWS)

• The biggest value of VIIRS is that it is part of a longer time-series of satellite chlorophyll measurements that extends back to 1997.

• Long-term climate-quality VIIRS ocean color data are needed for NMFS and NOS applications.
Thanks!

Obrigada!
